CEPII

Two Centuries of Bilateral Trade and Gravity Data: 1827-2014

Michel Fouquin & Jules Hugot

Highlights

- We provide about 1.9 million bilateral trade observations for 1827-2012.

- We provide about 40,000 observations of aggregate trade.

- We provide about 13,000 observations of nominal GDP.

- We provide about 13,000 observations of exchange rates regionalization of trade.

RESEARCH AND EXPERTISE
ON THE WORLD ECONOMY

▌ Abstract

This document provides a detailed description of the Historical Bilateral Trade and Gravity Data set (TRADHIST) that was put together for Fouquin and Hugot (2016) and designed for historical investigations of international trade. The data set is available on the website of CEPII. Specifically, the data set has been built to explore the two modern waves of globalization: the First Globalization of the nineteenth century and the post-World War II Second Globalization. The data set gathers five types of variables: i) bilateral nominal trade flows, ii) country-level aggregate nominal exports and imports, iii) nominal GDPs, iv) exchange rates, and v) bilateral factors that are known to favor or hamper trade, including geographical distance, common borders, colonial and linguistic links, as well as bilateral tariffs. This data is unique both in terms of temporal and geographical coverage. Overall, we gather more than 1.9 million bilateral trade observations for the 188 years from 1827 to 2014. We also provide about 42,000 observations on aggregate trade, and about 14,000 observations on GDPs and exchange rates respectively.

1. Introduction

This document provides a detailed description of the TRADHIST data set that was put together for Fouquin and Hugot (2016) and designed for historical investigations of international trade. The data set is available on the website of CEPII. Specifically, the data set has been built to explore the two modern waves of globalization: the First Globalization of the nineteenth century and the post-World War II Second Globalization. The dataset gathers five types of variables: i) bilateral nominal trade flows, ii) country-level aggregate nominal exports and imports, iii) nominal GDPs, iv) exchange rates, and v) bilateral factors that are known to favor or hamper trade, including geographical distance, common borders, colonial and linguistic links, as well as bilateral tariffs.[2] This data is unique both in terms of temporal and geographical coverage.

We adopt a systematic approach to collecting all of this data, to the exception of tariffs. For each variable, we merge the pre-existing (secondary) sources with additional data directly extracted from primary sources, including government publications, books and academic articles. In the end, we gather more than 1.9 million bilateral trade observations for the 188 years from 1827 to 2014. We also provide about 42,000 observations on aggregate trade (i.e. total imports and exports at the country level), and about 14,000 observations on GDPs and exchange rates respectively. The country pairs for which we collected bilateral trade are also associated with the great-circle distance and the shortest maritime distance between them, as well as with a set of dummy variables reflecting colonial and linguistic links. Nominal values have been systematically converted to the British pound sterling in order to make data internationally comparable.

Our most significant contribution is to expand the available bilateral trade data, both in terms of temporal and geographical coverage. Of the 1.9 million bilateral trade observations, more than 1.6 million concentrate on the 1948-2014 period; and about 97% of these observations comes from the Direction of Trade Statistics data set (International Monetary Fund, 2002 and 2015). Our contribution therefore concentrates on the period prior to 1948, for which we provide about 185,000 new observations, out of the 240,000 observations we report. For this period, we more than quadruple the amount of data available.

The structure of the data is bilateral: each observation pertains to a specific trade flow in a given year. Each observation is therefore country-pair, direction, and year-specific. The resulting panel is highly unbalanced, as the number of available bilateral trade flows dramatically increases over time. The origin and the destination country are respectively identified by the iso_o and the iso_d variables. The monadic variables – that are only country and year-specific – are duplicated whenever needed and attached to the origin or the destination country accordingly. Variables pertaining to the origin (destination) country are identified by the suffix $\_o$ ($\_d$). These variables include aggregate exports and imports, GDP and exchange rate.

Table 1 provides a summary of the main variables and Table 10 describes the variables.

---

[2]We also provide about 1,500 observations on aggregate tariffs, at the country level.

	Bilateral trade	Total exports	Total imports	GDP	Exchange rates	Bilateral tariffs
Dimension	country-pair direction-year[1]	country year	country year	country year	country year	country-pair direction-year
Number of observations	1,904,574	21,085	20,869	14,084	14,381	8,720
Number of country pairs	42,447					410
Number of countries[2]	319	247	245	218	145	172

[1] Each year, in theory, two trade flows pertain to each country pair: the exports from country A to country B and the exports from country B to country A.

[2] We use the word "country" to designate any administrative entity for which bilateral data is reported.

Table 1 – Summary of the main variables

2. Bilateral trade

Sources

We provide more than 1.9 million observed bilateral trade observations, of which about 185,000 points were directly collected from primary sources.[3] These data points are themselves extracted from about 250,000 observations that were collected from manuscripts.[4] The data also includes about 30,000 observations from the RICardo project (Accominotti et al., unpublished, 2010).[5] The left panel of Figure 1 reports the share of each source for the entire period. The right panel focuses on the period before 1948.[6]

Figure 2 details the sources from which the bilateral trade data is drawn. In some cases, several potential sources overlap. When this is the case, we systematically favor the data extracted from primary sources. The dashed line represents the share of the data that was already available through any of the secondary sources.[7] In the end, the data set brings 75% of novel observations for the pre-1948 period. Our contribution is even larger for the period between 1827 and 1869, for which we bring 82% of novel observations.

Table 2 compares our data with three bilateral data sets of reference. In order for these comparisons to be meaningful, we compare each of these data sets with the sub-sample of our own
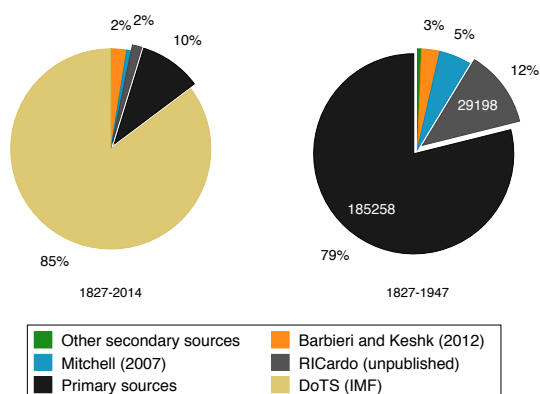

---

[3]i.e. customs archives. Records of the actual manuscript sources have been kept by the authors.

[4]This is due to the fact that each trade flow is in theory reported twice: by the exporter and by the importer. When the two sources were collected, the data set relies on the figure reported by the importer (see below for an explanation).

[5]We are particularly grateful to Guillaume Daudin and Béatrice Dedinger for sharing this data.

[6]1948 is the initial year covered by the extensive data from the Direction of Trade Statistics (International Monetary Fund, 2002 and 2015).

[7]In some cases, we replace data available from secondary sources by data directly extracted from a primary source. The data can therefore be directly matched with the original document from which it is extracted.

The legend reads clockwise from the top of the pies
The category "Other secondary sources" is too small to appear on the left pie

Figure 1 – Share of each source in the bilateral trade data
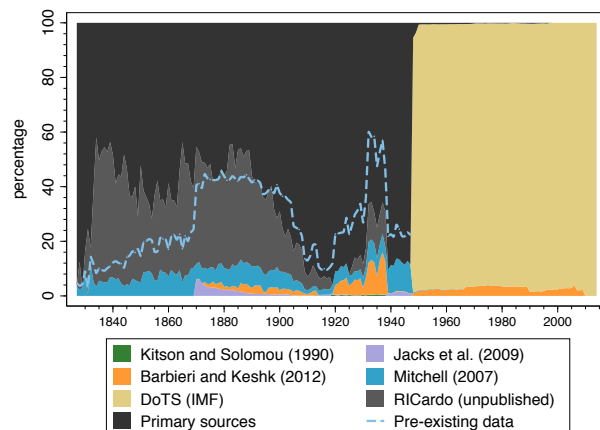

Figure 2 – Cumulative share of each source in the bilateral trade data

data that covers the same period. We restrict the samples to the years before 1948 because all the data sets rely on the same data from after that point (International Monetary Fund, 2002 and 2015). At constant time coverage and in terms of the number of observed trade flows, this data set is therefore more than twice larger than Pascali's (2014), about 11 times larger than Jacks et al.'s (2011) and more than 6 times larger than Barbieri and Keshk's (2012).

	Coverage	Our data	Pascali (2014)	Jacks et al. (2011)[1]	Barbieri and Keshk (2012)
Bilateral trade flows		**51,710**	23,000[2]		
Country pairs	1850-1900	**2,476**	1,000[2]		
Countries		**191**	129		
Bilateral trade flows		**238,850**		21,806	38,646
Country pairs	1870-1947	**14,497**		298	2,036
Countries		**295**		27	68

[1] We use the data from which the balanced sample used in Jacks et al. (2011) has been extracted.

[2] Approximated figures extracted from Pascali (2014), p.2.

Table 2 – Comparison of the bilateral trade data with three data sets of reference, at constant time coverage

Figure 3 lists for each year prior to 1948 the reporting countries that are identified in any of the sources (primary and secondary). Similarly, Figure 4 reports the countries for which national customs statistics (primary sources) are included in the data set. This includes the data that was directly collected as well as data from the RICardo project.[8] Countries in both figures are clustered by continent.

---

[8] The RICardo data set reports precisely the primary source from which each data point is extracted.
Figure 3 – Reporters from any source in the bilateral trade data: 1827-1947

Figure 4 – Reporters from primary sources in the bilateral trade data: 1827-1947

We provide a source variable ($SOURCE\_TF$) that indicates the source of each bilateral trade flow. Table 3 reports the correspondence between the codes that are used and the actual sources that can be found in the bibliography. For national sources, the first three letters correspond to the iso3 code of the reporting country (e.g. "FRA TABLEAU GAL" means that the data comes from a French source). Whenever there may be a doubt about the reporting country, a suffix is added to the source variable to make it explicit: "_IP" when the reporter is the importer and "_XP" when it is the exporter.[9] Table 3 also provides the number of observations extracted from each source as well as the initial and the last year for which the source is used.

Coverage

Figure 5 shows for each year the number of bilateral trade observations that are reported in the data set. Figure 6 restricts the sample to the period prior to 1948 and uses a linear y-axis instead of a logarithmic one. The two graphs distinguish between three types of bilateral trade observations. "Observed flow>0" denotes strictly positive observed trade flows. "Observed flow=0" denotes observed trade flows reported in the original source as nil. Data concerning the previous two categories is provided by the $FLOW$ variable. The first column of Table 1 reports the number of observations for this variable. Data for the third category is provided by the $FLOW\_0$ variable. This variable is set to zero when it seems reasonable to assume that the lack of observation is due to the trade flow actually being equal to zero. More precisely, $FLOW\_0$ is set to zero for trade with all the partners of a given reporting country for which information is missing, provided that the two following conditions are satisfied: i) the country reports trade with more than 30% of all the countries reported for the year of interest (by any other country) and ii) the country reports trade with at least 10 partners. When several country names overlap and actual trade data is reported for at least one of them, $FLOW\_0$ is set to missing.[10] $FLOW\_0$ adds about 800,000 (nil) trade observations to the 1,9 million actual observations reported by the $FLOW$ variable. Except for Figures 5 and 6, all the tables and figures in this document refer to the $FLOW$ variable, i.e. observed trade flows.

The increasing amount of data available over time can be attributed to three factors. First, it reflects the increasing number of existing countries, which mechanically increases the number of potential international trade flows.[11] Second, the increasing number of observed flows reflects the increasing number of existing country pairs that are actually engaged in bilateral trade.

---

[9]This applies to the following values of the $SOURCE\_TF$ variable: DOTS, FRACOLO, GBRCOLO, ITW, MITC and RIC, as those sources report trade flows for several countries.

[10]For example, "French West Indies" refers to the territories under French sovereignty in the Caribbean, including Guadeloupe and Martinique. If for a given year the United Kingdom reports positive or nil trade with Guadeloupe and/or Martinique, while other countries report trade with the French West Indies as a whole, $FLOW\_0$ will be set to missing for British trade with the French West Indies.

[11]In particular, the break ups of the Austro-Hungarian and the Ottoman Empires after World War I significantly increase the number of countries in the sample. Similarly, the discontinuity of the mid-1990s is largely due to the break up of the Soviet Union.
Figure 5 – Number of bilateral trade observations
Figure 6 – Number of bilateral trade observations: 1827-1947

Third, it can be a consequence of the easier access to primary sources for recent years, due to conservation issues and the difficulties in locating historical statistics for more ancient times.

Types of trade

Whenever possible, we report data on merchandise trade, excluding trade in services, bullion and species. Special import is favored over general import data and re-exports are excluded.[12]

Choice of reporting country

Any trade flow is in principle reported by both the exporter and the importer. Whenever possible, we use the source from the importer. Indeed, importers have a greater incentive to properly assess trade flows as they are commonly subject to duties. Figure 7 shows the composition of the data by status of the reporting country, whether exporter of importer. Some secondary sources do not specify which country is the reporter, hence the "Unknown reporter" category.[13]

Sample representativeness

Figure 9 plots the sum of the bilateral data against three estimates of world trade taken from the literature (Estevadeordal et al., 2003, Federico and Tena-Junguito, 2016, World Trade Organization, 2013). For most years prior to World War II, the sum of our bilateral data is greater than the existing estimates of world trade, which suggests that these estimates are underestimating the actual level of world trade.

---

[12]Special imports have the importing country as their final destination, whereas general trade is composed of special trade, together with transit trade.

[13]Those sources are: Mitchell (2007a,b,c), Jacks et al. (2011) and Barbieri and Keshk (2012).
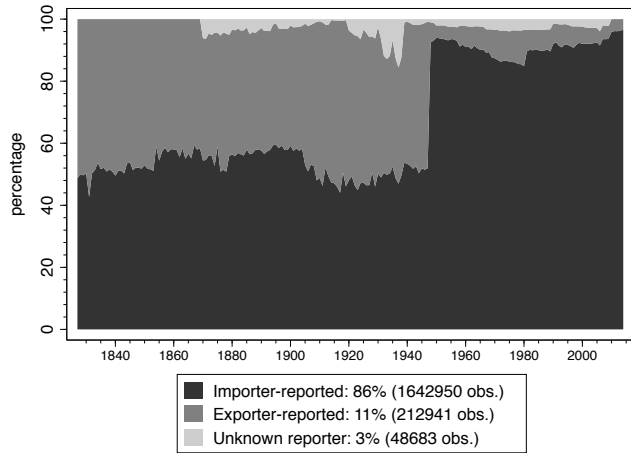

Figure 7 – Cumulative share of each reporter in the bilateral trade data
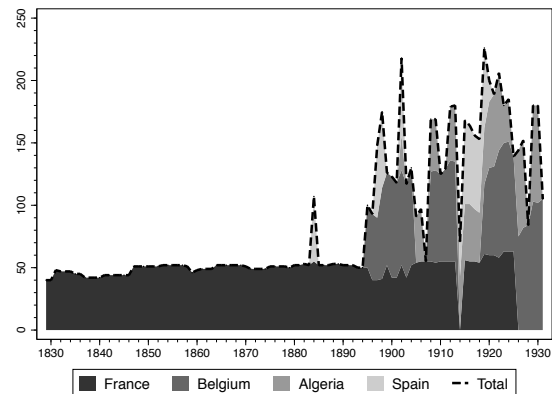

Figure 8 – Number of country pairs with available bilateral tariffs: 1829-1931

Figure 10 also plots the sum of the bilateral trade data, but this time against our data on total aggregate imports and exports, that we take as two additional proxies for total world trade. Total bilateral trade is often larger than total aggregate exports, which may sound counter-intuitive. This is because the bilateral trade data mostly relies on flows reported by importing countries, which are typically greater than the flows reported by exporters. On the contrary, Figure 10 shows that total bilateral trade generally lies closer to total aggregate imports. However, for some years, total bilateral trade is still greater than total aggregate imports. This is because both our bilateral and aggregate trade data is biased towards large countries. In turn, while in general the bilateral data includes large countries' exports to small ones (reported by the large origin country), aggregate trade data for small countries is often missing. Another interesting fact highlighted by Figure 10 is the high volatility in terms of coverage prior to 1870. This is simply because the trade reports for some countries could only be collected for certain years.[14]

Figure 11 compares the number of trade flows reported in our data to the number of theoretical trade flows, i.e. the number of pairwise combinations formed by the countries for which we report at least one trade flow. Figure 12 plots the number of observed flows as a share of the number of theoretical flows. From 1827 to 1947, our data covers between 5 and 25% of the theoretical observations. After 1948, our coverage lies between 55 and 85%.

Country definition

The country coding relies on the ISO-3 standard. The data identified by these codes pertains to national territories, excluding colonies. The countries that emerge from the unification of

---

[14]e.g. the spike of 1834 is due to a better coverage of British statistics, including bilateral trade with the British West Indies, and several countries of South America and Southern Europe. The spike of 1850 is due to data being available from Hamburg and the Hanseatic League for this year, as well as more extensive data for British trade.
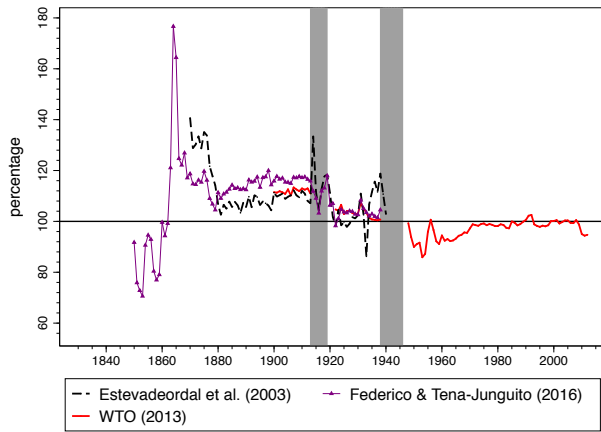

Figure 9 – Bilateral trade flows as a share of estimates of total world trade
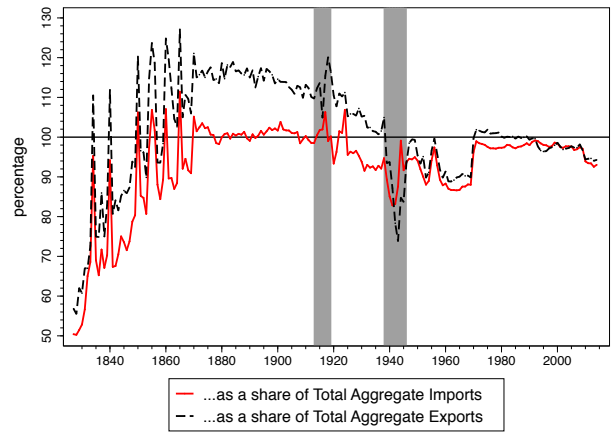

Figure 10 – Bilateral trade flows as a share of total aggregate imports and exports
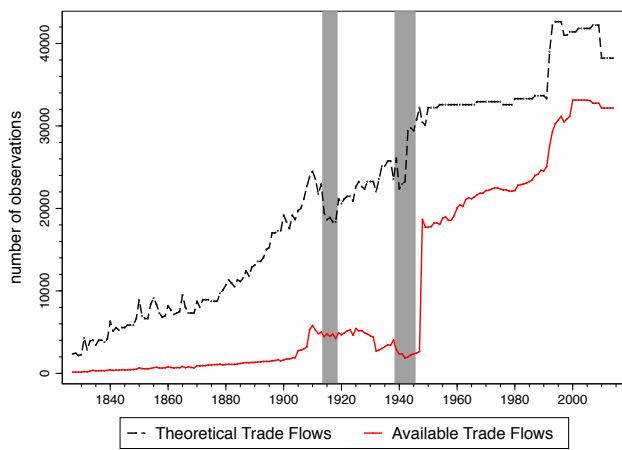

Figure 11 – Theoretical vs. Observed bilateral trade flows
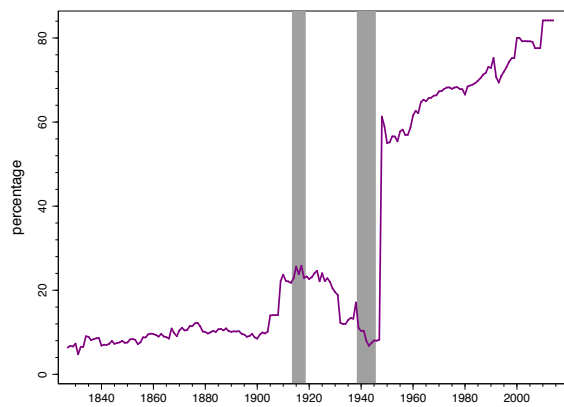

Figure 12 – Observed trade flows as a share of theoretical trade flows

several polities (e.g. Germany) or, on the contrary, from the collapse of a country (eg. Czech Republic and Slovakia) are considered new countries. When the borders of the country are close enough to a present-day country, we use the corresponding ISO-3 code.[15] For the entities that can hardly be matched with any present-day country, we create our own codes, listed in Table 4.

3.   Bilateral tariffs

The data set reports about 8,000 observations of bilateral customs duties-to-imports ratios. This data can be used to proxy the level of bilateral tariff protection. Figure 8 shows the number of country pairs for which this ratio is available. The sources are always identical to those used for the bilateral trade data.

4.   Aggregate trade

The data set reports about 40,000 observations on total exports and imports. Each observation pertains to a country in a given year. Table 7 shows how the source variables attached to aggregate trade variables – $SOURCE\_XPTOT\_o(d)$ and $SOURCE\_IPTOT\_o(d)$ – should be understood.

Figure 13 shows the growth of aggregate exports across the two waves of globalization. From 1827 to 1913, world trade grew on average by 3.9% per year in nominal terms. After World War II, average world trade growth increased to 11.4% per year, with two phases of particular dynamism: right after the war and in the 1970.

Figure 14 shows that total imports are greater than total exports for almost all years. This is due to two reasons. First, customs conventions specify that trade is reported "Free on Board" (F.O.B.) to the exporting country and including the cost of insurance and freight (C.I.F.) at destination. Second, importing countries have greater incentives to carefully report in-flowing trade as governments generally levy taxes on imports. Note that the gap closes from more than 10% in the nineteenth century down to less than 5% after World War II and almost zero in the most recent years.

Figures 15 and 16 respectively report the availability of aggregate exports and imports data from 1827 to 1947. Figure 17 reports the number of observations for each year.

5.   Aggregate tariffs

We provide about 1,500 observations of customs duties-to-imports ratios, at the country level. This measure can be used as a measure of the level of countries' aggregate trade protection.

---

[15]e.g. "DEU" identifies Germany for 1871-1888, even if Hamburg, Lübeck and Bremen only join the German Empire in 1888. On the contrary, Austria-Hungary disappears in 1918, while Austria and Hungary appear in 1919.
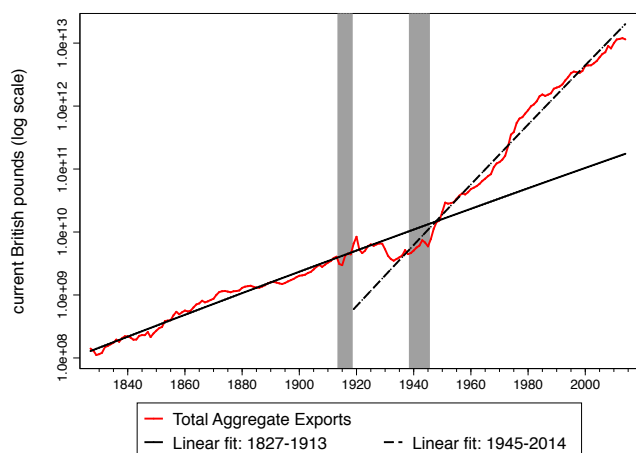

Figure 13 – Total aggegate exports
Figure 14 – Total aggregate exports as a share of total aggregate imports

Table 6 shows how the source variable should be understood. Figure 17 also reports the number of countries for which my measure of aggregate tariff protection is available.

Table 6 – Correspondence table for the aggregate tariff source variable
(Sorted by the number of observations in the data set)

6. GDP

We provide about 14,000 observations on current price GDP. Most of the data before 1960 is extracted from a recent literature which aims to reconstruct historical national accounts. Figure 17 reports the number of countries for which we provide GDP data. Figure 18 lists the country-years for which we report GDP data, prior to 1960.[16] Table 7 shows how the source variables attached to GDP variables – $SOURCE\_GDP\_o(d)$ – should be read.

---

[16]1960 is the initial year covered by the extensive World Bank (2015) data.
Figure 15 – Reporters in the aggregate export data: 1827-1947
Figure 16 – Reporters in the aggregate import data: 1827-1947
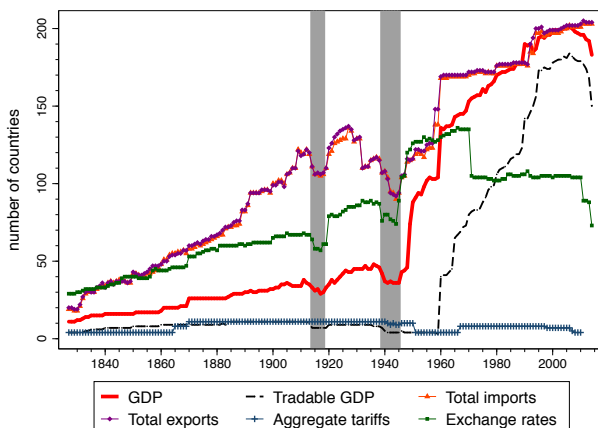

Figure 17 – Availability of country year-specific variables

We also provide four variables – $SH\_PRIM_{o(d)}$ and $SH\_SECD_{o(d)}$ – that respectively report the share of the primary and the secondary sector in the GDP of the origin (destination) country. The sources are always identical to those used for the GDP data. Figure 17 also reports the number of countries for which we were able to compute tradable GDP as the cumulative share of the primary and secondary sectors in GDP.

7. Exchange rates

We provide exchange rates vis-à-vis the British pound sterling. The exchange rate variable is set to the British pound value of one local currency unit. Figure 17 reports for each year the number of countries for which exchange rate data is available. Table 8 shows how the source variables should be understood. Figure 19 reports for each year before 1948 the countries for which we provide exchange rate data.[17]

_____

[17]The data set of the International Monetary Fund (2012) reports exchange rates from 1948 onward.

8.   Distance variables

We provide seven different measures of bilateral distance extracted from the CEPII's $GeoDist$ data set.[18] $Dist$ is a city population-weighted mean of the great-circle distance between each pair of countries[19]. For the reporting entities that no longer exist, we use the population-weighted bilateral distance from the nearest present-day country. $Dist_{o(d)}$ is a measure of countries' internal distances set to $.67\sqrt{area/\pi}$[20]. Figure 20 breaks down the bilateral trade data using the $Dist$ variable.

$SeaDist$ is a measure of the shortest maritime distance between two countries. This variable is set to $Dist\_nocanal$ before 1870, to $Dist\_suezonly$ for 1870-1920, $Dist\_twocanals$ for 1921-1966, $Dist\_panaonly$ for 1867-1975, and $Dist\_twocanals$ for 1976-2014. The 1967-1975 period corresponds to the closing of the Suez Canal, consecutive to the Six-Day War. All maritime distances have been extracted from the Vesseltracker.com (2014). We first selected the largest port of each country (two ports when the country is flanked by two different oceans). Then, for each country-pair, we chose the shortest maritime distance between any of the ports of both countries. For landlocked countries, we chose the closest foreign port. We do not report any value if the country pair shares a border and at least one of the two is landlocked (e.g. Paraguay-Argentina).

9.   Other variables

Geographic location

We provide variables identifying the continent and the sub-continental region of each origin and destination country. Table 9 summarizes the values taken by those four variables: $CONTI_{o(d)}$ and $REGIO_{o(d)}$. In Figure 21, we use this information to break down the bilateral trade data by trade route. The left panel of Figure 22 reports the share of various regions in the bilateral export data. The right panel reports the same information for the aggregate export data. The almost perfect matching between the two panels indicates that our bilateral data is representative of world trade.
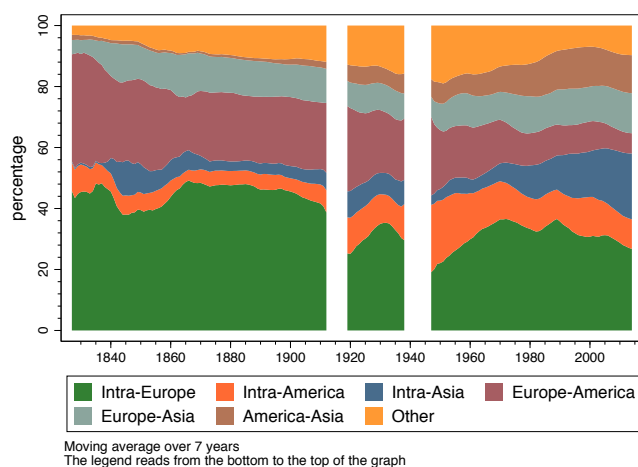

---

[18]A detailed description of the variables can be found in Head and Mayer (2002) and Mayer and Zignago (2011).
[19]Variable $distw$ from the $GeoDist$ data set.
[20]Variable $dist\_int$ from the $GeoDist$ data set. For a detailed discussion, see Head and Mayer (2002), pp.10-11.

Table 9 – Correspondence table for geographic location variables

Figure 22 – Cumulative share of bilateral and aggregate exports, by region
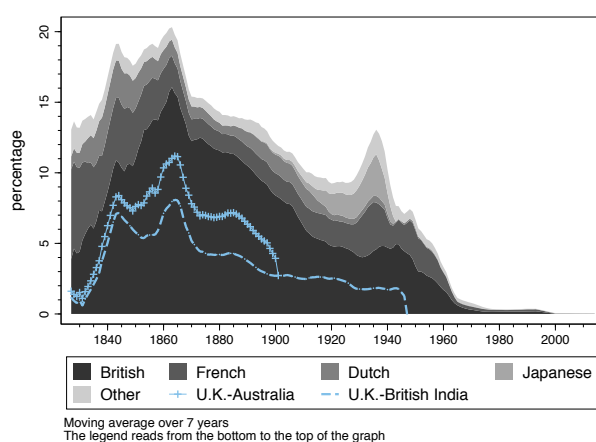

Figure 23 – Cumulative share of colonial bilateral trade, by colonizer

Colonial ties

We provide several variables to identify the colonial status of country pairs. $Curcol$ is set to unity if the pair is in a colonial relationship in a given year. When $Curcol$ is set to unity, $Metro$ and $Colo$ respectively identify which of the origin or the destination country is the metropolis and which is the colony. $Evercol$ is set to unity if the pair ever was in a colonial relationship. If $Evercol$ is set to unity, $Indepdate$ gives the year of independence of the former colony.

We also provide monadic variables that identify the colonial status of each country. $Curcol_{o(d)}$ are two dummy variables that are set to unity if the origin (destination) country is a colony of any country during the year of interest. $Evercol_{o(d)}$ is set to unity if the origin (destination) country ever was a colony. $Indepdate_{o(d)}$ give the year of the latest independence of the origin (destination) country.

This data is an extended version of the data from Head et al. (2010), that covers 1948-2006. Figure 23, combines the $Curcol$ variable with the bilateral trade data, to identify the share of colonial trade in the data set. Figure 23 notably emphasizes the overwhelming role of Britain in colonial trade.

Variable	Dimension	Description
iso_o(d)	country	Origin (destination) country iso3 code
year	year	Year
FLOW	country-pair-direction-year	Bilateral trade flow in current British pounds
FLOW_0	country-pair-direction-year	Bilateral trade flow likely equal to zero
SOURCE_TF	country-pair-direction-year	Source for the bilateral trade flow
GDP_o(d)	country-year	GDP of the origin (destination) country in British pounds
SOURCE_GDP_o(d)	country-year	Source of GDP data
SH_PRIM_o(d)	country-year	Share of the primary sector in the origin (destination) country's GDP, in percentage
SOURCE_SH_PRIM_o(d)	country-year	Source for the share of the primary sector
SH_SECD_o(d)	country-year	Share of the secondary sector in the origin (destination) country's GDP, in percentage
SOURCE_SH_SECD_o(d)	country-year	Source for the share of the secondary sector
IPTOT_o(d)	country-year	Total imports in current British pounds
SOURCE_IPTOT_o(d)	country-year	Source of total imports data
XPTOT_o(d)	country-year	Total exports in current British pounds
SOURCE_XPTOT_o(d)	country-year	Source of total exports data
BITARIFF	country-pair-direction-year	Tariff imposed by country *d* on imports from country *o* (i.e. ratio of bilateral duties to imports, in percentage)
TARIFF_o(d)	country-year	Average tariff imposed by country *o* (*d*) (i.e. ratio of total duties to imports, in percentage)
SOURCE_TARIFF_o(d)	country-year	Source for aggregate tariffs
Dist	country pair	Population-weighted-great-circle distance, in km. (see: variable *distw*, p.11 in Mayer and Zignago (2011))
Dist_o(d)	country	Internal distance of the origin (destination) country computed as: $.67\sqrt{area/\pi}$, in km. (Head and Mayer (2002))
SeaDist	country-pair-year	Bilateral shortest maritime distance, in km.
Dist_nocanal	country pair	Bilateral shortest maritime distance without the Suez and the Panama canals, in km.
Dist_suezonly	country pair	Bilateral shortest maritime distance with the Suez canal and without the Panama canal, in km.
Dist_twocanals	country pair	Bilateral shortest maritime distance with both the Suez and the Panama canals, in km.
Dist_panaonly	country pair	Bilateral shortest maritime distance with the Panama canal and without the Suez canal, in km.
Comlang	country-pair	Dummy set to 1 if at least one language is spoken by more than 9% of the population in both countries
Contig	country-pair	Dummy set to 1 if the countries are contiguous
Curcol	country-pair-year	Dummy set to 1 if the origin and the destination country are in a colonial relationship
Metro	country-pair-year	iso3 code of the metropolis for colonial pairs
Colo	country-pair-year	iso3 code of the colony for colonial pairs
Curcol_o(d)	country-year	Dummy set to 1 if the country is a colony
Evercol	country pair	Dummy set to 1 if the origin and the destination country ever were in a colonial relationship
Evercol_o(d)	country	Dummy set to 1 if the country ever was a colony
Indepdate	country pair	Year of independence for colonial pairs
Indepdate_o(d)	country	Year of latest independence
XCH_RATE_o(d)	country-year	British pounds per local currency unit
SOURCE_XCH_o(d)	country-year	Source for the exchange rate
CONTI_o(d)	country	Continent of the origin (destination) country
REGIO_o(d)	country	Sub-continental region of the origin (destination) country
